1 Introduction

One prevalent use of network processors is the implementation of devices that perform packet forwarding based on IPv4 unicast destination addresses. There are at least two databases needed for IP forwarding, one being the Routing Information Base (RIB), which resides on the control plane, and the other being the Forwarding Information Base (FIB), which network processors may access on the forwarding plane. Ingress packets have their destination IP address extracted and used as a lookup key in the FIB. Assuming a match is found, this forwarding information typically provides a next hop IP address and an egress interface, which can be used to reach this next hop. The next hop is usually the IP address of the router that provides a path to the final destination of the packet. The next hop can also be an MPLS Label Switched Path (LSP) defining a Next Hop Label Forwarding Entry (NHLFE). The forwarding information located in the FIB may entail not only next hop information, but also other characteristics, such as QoS based on DiffServ, or encapsulation schemes, such as MPLS tunneling.

The RIB may be created by static configuration or via dynamic routing protocols, such as OSPF and BGP. Often, such application layer software will interface with an intelligent Route Table Manager (RTM) component, whose job is to manage the RIB and maintain the FIB used by the forwarding plane IP packet handling. MPLS information concerning configured LSPs to be used as a possible next hop for a destination prefix may be passed to RTM by MPLS protocols like LDP and RSVP. Usually, the RIB contains all the routes known to all routing protocols, and the FIB is the “active” subset of those routes—the ones chosen as best for forwarding. The RTM can use NPF defined IPv4 Unicast Forwarding Service API function calls to manage an IPv4 FIB.

Another component of IPv4 packet forwarding is the description of a method to resolve a next hop destination IPv4 address into the associated media address. There are many ways to resolve Layer 3 to Layer 2 address mapping, depending upon link layer. For example, in the case of Ethernet links, the Address Resolution Protocol (ARP, defined in RFC 826) is used for this purpose.

A basic example system might have the following characteristics:

- An RTM managing a RIB in the control plane will use NPF IPv4 Unicast Forwarding Service API calls to maintain a FIB for use by a network processor.
- An NP in the forwarding plane has knowledge and control of one or more layer 3 interfaces.
- The NP has knowledge of, and access to, a FIB.
- Each FIB is associated with one or more layer 3 interfaces.
- The FIB has been created at some point and is referenced by a unique handle.
- One or more NP’s may be present in the system.

For example, the initial ingress forwarding steps with this model might be:

- A packet arrives on an interface.
- The FIB is selected based on the incoming layer 3 interface.
- The longest prefix match lookup of the packet's destination IPv4 address is done using this particular FIB.
The following two figures may prove useful in understanding the specification of the IPv4 Unicast Forwarding Service API.

In Figure 1, the RTM oversees the management of routes provided by routing protocols and maintains a single RIB. Using the IPv4 Unicast Forwarding Service API, the RTM defines and populates the FIB, knowing only about one FIB which is identified by a unique FIB handle. A particular FIB may be replicated in different NP devices. Such replication may be done by the Services API implementation or by some system-aware middleware below it.

Yet another design is worth consideration. This implementation might represent a system that has created multiple virtual routers in order to realize a Virtual Private Network. In this scheme, isolation is provided between routing domains by maintaining independent RIBs, and as a consequence, unique instances of their associated FIBs. In this situation, the control plane has knowledge of two unique FIBs and will be dealing with two unique FIB handles.
The introduction, so far, has presented high level concepts related to IPv4 Unicast Forwarding and the placement of various components. This document acknowledges the wide range and variety of target environments for control plane applications and NPs. In Section 3, *API Usage Model*, in depth information is provided regarding the representation of a FIB and the affect this has on the design of the IPv4 Unicast Forwarding Service API.

The remainder of this document is organized as follows:

- Section 3 describes forwarding information base models and usage of the corresponding APIs.
- Section 4 describes the data structures, callbacks, return values, and events used in the IPv4 Unicast Forwarding Service API.
- Section 5 describes the function calls used in the IPv4 Unicast Forwarding Service API.
- Section 6 provides references to other relevant documentation.
- Section 7 summarizes the function call names by category and also provides a list of events.
- The Appendix contains an IPv4 Unicast Forwarding header file.
1.1 Assumptions and External Requirements

- For a better understanding of this specification, it is assumed that the reader has an understanding of the concepts and guidelines presented in the following NPF Software Implementation Agreements:
  - Software API Conventions (Revision 1, August 2002).
  - API Software Framework (Revision 1, August 2002).
  - Interface Management APIs (Revision 1, August 2002).
- While the term “table” is used throughout this document, this is a convenience to describe the model. There is no requirement that tables be implemented below the API, either on the control plane or the forwarding plane.
- The following concepts are contained in the NPF Software Implementation Agreement – Interface Management APIs (Revision 1, August 2002):
  - The description of how logical layer 3 interfaces are associated with a particular FIB.
- All API calls are considered asynchronous in nature, unless otherwise specified. The definitions of synchronous and asynchronous behavior are specified by the NPF Software Implementation Agreement – Software API Conventions (Revision 1, August 2002).
- As specified in the Software API Conventions (Revision 1, August 2002) Implementation Agreement, Section 6.4, memories that are used to hold values that are passed as parameters are “owned” by the side that allocated them. An owner of a memory is responsible for de-allocating this memory when it is no longer used.

1.2 Scope

This specification describes data structures for IPv4 unicast forwarding and address resolution. The data types and structures generally used by all API specifications are defined by the NPF Software Implementation Agreement - Software API Conventions (Revision 1, August 2002) document; however, IPv4 specific structures are defined in this document.

This specification describes Service API definitions for IPv4 unicast forwarding and address resolution. The API function details will include input/output parameters, return code specifications and detailed usage notes specific to each invocation.

This specification provides details regarding the handling of asynchronous events and expected responses from API function invocations, including specifications for completion callback and event handler routine registration and deregistration.

1.3 Dependencies

This document depends on the NPF Software Implementation Agreement - Software API Conventions (Revision 1, August 2002) document for basic type definitions as well as the IPv4 network address, ATM VPI/VCI, and MAC address structures.

The document also depends on the NPF Software Implementation Agreement, Interface Management APIs (Revision 1, August 2002) document for the definition of NPF_IfHandle_t, and MPLS Forwarding Service API Implementation Agreement for the definition of LSP Handle.
2 API Usage Model

Depending upon the networking environment, control plane application design and forwarding plane NP architecture, a Forwarding Information Base (FIB) may be modeled in several ways. This document considers two modes for organizing and manipulating the IPv4 unicast forwarding information at the Service API level. Since it is customary to describe a Forwarding Information Base (FIB) in terms of a table data structure, this abstraction is used throughout the rest of this specification.

The first mode, called the unified table mode, uses a single table for structuring and managing IPv4 unicast forwarding information. The second mode, called the discrete table mode, uses separate prefix and next hop tables for structuring and managing IPv4 unicast forwarding information. Additionally, both modes represent address resolution information using a separate address resolution table.

The modes do not imply that the underlying NP forwarding elements support one or the other of these modes. Since this is an NPF Services API, the application has no knowledge of the individual NP forwarding elements, so the modes only specify the application layer interface to the IPv4 Unicast Forwarding services provided by the system. The models each represent a shared view between an application and the Service API implementation.

For example, an NP forwarding element may implement discrete mode prefix and next hop tables, whereas the control plane routing application may organize its FIB information in a unified model. In such a case, it is appropriate for the application to use the unified mode API function calls. The IPv4 Unicast Forwarding Services API implementation or some other software below it on the CP or NP forwarding element, would then be responsible for mapping the unified parameters to a suitable format for the discrete mode organization of the NP.

The two modes and their data entities are representative of a large number of system implementations. However, based on a desire for maximum interoperability and a perceived current market prevalence of routing applications designed using a unified mode, it is so stated:

Compliant implementations of the IPv4 Unicast Forwarding Service API specification MUST implement the unified table mode, but MAY also implement the discrete table mode, according to segment needs and product capabilities.

With the above requirements statement, it is acknowledged that certain combinations of application and NP architecture choices may place an extra burden upon either the application or the IPv4 Service API implementation. Therefore, the decision to offer an optional discrete mode is prompted primarily to alleviate two concerns:

- First, excessive amounts of storage may be required to maintain state information if the Service API mode does not match the underlying forwarding element representation. This is particularly important because many network processors have imbedded control points with limited storage.
- Second, the amount of processing needed to manage a table model which does not match the underlying representation could lead to unreasonable delays in transmitting changes to the network processor.
2.1 Unified Table Model

Implementations that utilize the unified table model to represent IPv4 unicast forwarding information use a single data entity, which shall be subsequently referred to as a “FIB Table.” This table is comprised of entries, each one consisting of a prefix and an array of next hop information.

To facilitate capabilities such as load balancing or ECMP, the next hop array may contain information for one or more next hops. Each next hop array is essentially a set of next hops. There are different flavors of next hop, each of which dictates a different forwarding action. The basic, direct attach, and remote types forward packets through the network processor. These forwarding next hop types have an IP destination address and an egress interface included in their definition. Other flavors of next hop indicate other actions such as discard the packet, forward the packet to the control plane or map to MPLS LSPs as in the FEC to NHLFE mapping (FTNs).

Figure 3 illustrates the conceptual layout of a FIB table and several table entries. In this structure, the unique “key” used to reference an entry is the prefix element.

Address resolution in the unified table mode is modeled separately, using the distinct address resolution functions and data types described later in this specification.

---

1 The term FIB is an acronym used for a Forwarding Information Base and is used throughout the document when referring to the forwarding information abstraction. However, note that the term “FIB Table” has been chosen to refer to the unified mode data entity used to model forwarding information. Therefore, it is used in the nomenclature of the unified mode data structures and API function names.
2.2 Discrete Table Model

Implementations that utilize the discrete table model to represent IPv4 unicast forwarding information use two separate data entities, which shall be subsequently referred to as the “Prefix Table” and the “Next Hop Table.”

The prefix table is comprised of entries, each one consisting of a prefix and a next hop identifier that uniquely indicates an entry in a next hop table. The next hop table is comprised of entries, each one consisting of a next hop identifier and an array of next hop information. As with the unified mode FIB table, the next hop array can contain one or more elements of next hop information.

In order to forward a packet, each IP destination address specified in the prefix must have one or more next hops associated with it. In the discrete model, this association is provided by the next hop identifier, which correlates a prefix table entry to an entry in the next hop table. This “split” table model provides several benefits in some system designs. For example, some classes of high-performance networking nodes (e.g. – BGP routers) require optimal FIB updates when a set of routes change. With a discrete model implementation, it may be possible to efficiently update forwarding information by altering a subset of next hop table entries. Whereas, in a unified model, it may be required that a larger set of FIB table entries be modified to accomplish the same forwarding information update.

Figure 4 illustrates the conceptual layout and relationship of the prefix table and next hop table. In the prefix table, the unique “key” used to reference an entry is the prefix element. In the next hop table, the unique “key” used to reference an entry is the next hop identifier.

![Figure 4 – Discrete Table Model](image)

An application may create multiple prefix and next hop tables. The API defines a function that creates a relationship between a prefix table and a next hop table. Such relationships can be one-to-one, so that there is a prefix table corresponding to each next hop table. Additionally, the relationship may be many-to-one, in which two or more prefix tables share a single next hop table. A one-to-many relationship, in which a single prefix table is associated with multiple next hop tables, is not supported.
The application is responsible for the allocation and use of next hop identifier values. It may choose any values it wants, and it may re-use them in any way it wants. An application should create a next hop table entry for each new next hop identifier it uses in the prefix table. If an NP forwarding element references a prefix table entry containing a next hop identifier that is not assigned to a valid next hop table entry, the implementation may generate an event to signal the application of the problem.

Address resolution in the discrete table mode is also modeled separately, using the distinct address resolution functions and data types described later in this specification.

### 2.3 Address Resolution Table

For both the unified and discrete model, the next hop information in a next hop array element contains IP-level address and egress interface information. In order to forward a packet, the next hop IP address and egress interface must be resolved to a layer 2 address. The address resolution table makes this possible, by taking an IP address and egress interface as key fields, and providing a media specific address.

To provide further flexibility, note that the three pieces of information that comprise an address resolution table entry are also defined in the next hop information in a next hop array element. This allows some implementations to avoid an additional address resolution table lookup because the media address is available immediately when the next hop is determined.

An address resolution table entry contains media specific information for IP address and egress interface pairs. Because there are many types of physical media, the media address component is defined as a type field, indicating the media type, and a union of media address definitions.

Figure 5 illustrates the conceptual layout of the address resolution table. As mentioned, the unique “key” used to reference an entry is the combination of the IP address and the egress interface identifier.

Figure 5 - Address Resolution Table Model - (Ethernet example)
2.4 **API Usage Guidelines**

Application clients of the IPv4 Services API will create one or more instances of IPv4 tables to control the IPv4 forwarding of a device. In order to determine what type of table to create, implementations may use the query methods defined in section 5.5 to determine which table modes are supported and which mode provides the best performance. Once an application has determined the supported and preferred modes of operation, it may create one or more Prefix, Next Hop, FIB, and Address Resolution tables, using the functions associated with each table type to populate and monitor each table.

Some implementations may only support a unified table mode of operation. Unified table-only implementations will return an error code if discrete prefix or next hop table functions are invoked. Unified and discrete table implementations will support the address resolution functions.

Implementations that support both discrete and unified table mode of operation may be used in both modes at the same time, however, it is assumed that each mode is used for a unique and distinct FIB. In other words, the two different modes should not be used to operate on the same FIB.

The unified FIB table functions may not be used with the discrete next hop and prefix table handles and discrete next hop and prefix table functions may not be used with unified FIB table handles. Type checking will detect such misuse at compile time, or, if not detected, the implementation will return errors when discrete handles are used with unified functions and vice versa.

![Figure 6 - Usage Models](image-url)
3 Data Types

This section defines data types that are used in the unified and discrete mode implementations as well as shared data types such as return codes, table mode query values, next hop information and IPv4 address resolution data structures. In addition, this section provides data structures used for asynchronous completion callbacks and event notifications.

3.1 Common Data Types

3.1.1 Table Mode Query Data Types

This section defines the types used by an application to query the supported and preferred table modes of an implementation.

```c
typedef enum {
    NPF_IPV4UC_UNIFIED_ONLY = 1,
    NPF_IPV4UC_BOTH_SUPPORTED = 2
} NPF_IPv4UC_SupportedMode_t;
```

```c
typedef enum {
    NPF_IPV4UC_DISCRETE_PREFERRED = 1,
    NPF_IPV4UC_UNIFIED_PREFERRED = 2,
    NPF_IPV4UC_NO_PREFERENCE = 3
} NPF_IPv4UC_PreferredMode_t;
```

3.1.2 Prefix Data Types

This simple data type provides a more meaningful name for the structure that defines an IPv4 address and prefix length.

Also note that even though the NPF_IPv4NetAddr_t type is used here, it is actually defined in the Software API Conventions, Revision 1, August 2002.

```c
/*
 * IPv4 unicast prefix type
 */
typedef NPF_IPv4NetAddr_t NPF_IPv4UC_Prefix_t;
```

3.1.3 Next Hop Array Data Types

A Next Hop Table entry consists of a Next Hop identifier and a Next Hop array, whereas, a FIB Table entry consists of a prefix and a Next Hop array. In each case, there exists a Next Hop array which defines one or more next hops with a count to indicate the number of next hops in the array.

- nextHopCount – The number of next hops in the Next Hop array.
- nextHopArray – An array of next hops. If multiple next hops are specified, the weight member of the NPF_IPv4UC_NextHop_t structure is used to determine which data packets to forward to each next hop. The algorithm used to select particular next hops is implementation dependent.
/ IPv4 unicast Next Hop Array: nextHopArray points to an array (one or more) of NPF_IPv4UC_NextHop_t structures. nextHopCount indicates how many next hops are in the array. */

typedef struct {
    NPF_uint32_t nextHopCount;
    NPF_IPv4UC_NextHop_t *nextHopArray;
} NPF_IPv4UC_NextHopArray_t;

Each member of the nextHopArray specifies a particular next hop definition, with the following components:

- **type** – The type of the next hop:
  - basic – The forwarding behavior for a basic entry is to send the packet to the Next Hop IP address in the associated NPF_IPv4UC_IPv4NextHop_t structure.
  - directAttach – A directly attached subnet means that the IPv4 destination address is on a directly attached network, and the Next Hop IP address in the associated NPF_IPv4UC_IPv4NextHop_t structure is either absent or is identical to the IPv4 destination address. The forwarding behavior is modified by selecting a media address corresponding to the destination IP address, not a next hop router IP address. Support for this type is optional.
  - sendToCP – Forwarding behavior for this type is for the network processor to send the packet to a Control Plane. Other than type, no other fields are used for this kind of next hop.
  - discard – The network processor counts the packet and then drops it. Other than type, there are no other fields for this kind of next hop.
  - remote – The next hop IP address in the associated NPF_IPv4UC_IPv4NextHop_t structure is an address of a remote router through which this packet will be forwarded, not the immediate next hop IP address. The egress interface handle MAY be absent. Route table entries with prefixes learned through the BGP protocol MAY use these Next Hop Entries. Forwarding behavior modification, if any, is the implementer’s choice. One possible use of the Remote type is in optimization of prefix table updates on BGP routes with an IBGP switch over. Support for this type is optional.
  - mpls LSP – The packet is to be encapsulated with an MPLS Header and forwarded on the LSP specified.

- **weight** – Has meaning when the Next Hop array contains a list of multiple interchangeable next hops. One possible use may be for the forwarder to assign each packet to one next hop in the list, while trying to keep the link bandwidth utilization of each proportional to its own weight, relative to the rest of the list. This parameter can be used in various environments, such as link bundling, ECMP, traffic engineering and others. How this value is assigned and used is outside the scope of this document.
/*
 * Next hop structure;
 */
typedef struct {
    NPF_IPv4UC_NextHopType_t type;
    NPF_uint16_t   weight;
    union {
        NPF_IPv4UC_IPv4NextHop_t ipv4NextHop;
        NPF_MPLS_LSP_Handle_t  lspHandle;
    } u;
} NPF_IPv4UC_NextHop_t;

typedef enum {
    NPF_IPV4UC_NH_BASIC         =  1,
    NPF_IPV4UC_NH_DIRECT_ATTACH =  2,
    NPF_IPV4UC_NH_SEND_TO_CP    =  3,
    NPF_IPV4UC_NH_DISCARD       =  4,
    NPF_IPV4UC_NH_REMOTE        =  5,
    NPF_IPV4UC_NH_MPLSLSP     =  6
} NPF_IPv4UC_NextHopType_t;

An IPv4 Next hop type structure holds:
- egressInterface – The handle of the interface representing the egress path to which the next hop router is connected.
- nextHopIP – The IPv4 address of the next hop router or end system.
- mediaAddress – Optional lower layer information associated with the next hop IP address. This parameter may be used to populate lower layer information in the FIB, if the FIB is organized to contain such information. However, some implementations hold lower layer information in a different table; the address resolution table. In such a case, the address resolution table function calls will provide the means to manipulate the lower layer information. This lower layer information may be provided by one means or the other\(^2\), but in general, both methods should not be used together. If an implementation does provide the means to use both this parameter and the address resolution table function calls, the preference of which function call to use is application dependent.

/*
 * IPv4 unicast next hop type structure: used only for
 * NPF_IPV4UC_NH_BASIC, NPF_IPV4UC_NH_DIRECT_ATTACH, and
 * NPF_IPV4UC_NH_REMOTE types.
 */
typedef struct {
    NPF_IfHandle_t   egressInterface;
    NPF_IPv4Address_t   nextHopIP;
    NPF_MediaAddress_t  mediaAddress;
} NPF_IPv4UC_IPv4NextHop_t;

An MPLS LSP Next hop type holds:
- lspHandle – The handle of the MPLS LSP, as defined in the MPLS SAPI, and provided by the signaling protocol

\(^2\) An implementation MAY ignore L2 addresses from the IPv4 API, if it has a better source for the information, such as ARP directly implemented on a line card.
3.1.4 Address Resolution Data Types

This section defines the IPv4 control structures that are required to perform IPv4 address to physical address resolution. There are a number of ways of performing this resolution, Address Resolution Protocol (ARP, RFC 826) being one widely-known method.

An Address Resolution Table entry consists of an IP address, an interface handle and a media specific address. These components are defined in a single NPF_IPv4UC_AddResEntry_t structure.

- IP_Address - The protocol address for which a media-specific address binding is defined.
- interfaceHandle – The interface which is associated with this entry.
- mediaAddress - The media address associated with the specified protocol address. Examples might be a 6 byte Ethernet MAC address or an ATM VPI/VCI.

```
/*
 * IPv4 unicast Address Resolution entry:
 */
typedef struct {
     NPF_IPv4Address_t  IP_Address;
     NPF_IfHandle_t   interfaceHandle;
     NPF_MediaAddress_t mediaAddress;
 } NPF_IPv4UC_AddResEntry_t;
```

When performing a query of the address resolution table, the NPF_IPv4UC_AddResKey_t structure defines the search key.

```
/*
 * This structure contains the key of an Address Resolution
 * table entry, consisting of IP address and interface handle.
 */
typedef struct {
     NPF_IPv4Address_t  IP_Address;
     NPF_IfHandle_t   interfaceHandle;
 } NPF_IPv4UC_AddResKey_t;
```

For an Address Resolution Table query, the response structure is identical to the NPF_IPv4UC_AddResEntry_t structure defined above. Instead of duplicating this structure with a unique name, a simple typedef is defined and this structure name is then used in the completion callback asynchronous response union.

```
/*
 * This simple data type provides a more meaningful name for the
 * structure used in the address resolution asynchronous callback data.
 */
typedef NPF_IPv4UC_AddResEntry_t NPF_IPv4UC_AddResQueryResp_t;
```

The media specific address structure contains a type field to identify the particular format.

- type – The type of address contained in the mediaAddress parameter.

```
/*
 * Media Address structure:
 */
```
typedef struct {
    NPF_MediaType_t type;
    union {
        NPF_MAC_Address_t MAC_Address;
        NPF_VccAddr_t ATM_Vc;
    } u;
} NPF_MediaAddress_t;

/*
 * Media type definition:
 */
typedef enum {
    NPF_NO_MEDIA_TYPE = 1,
    NPF_MAC_ADDRESS = 2,
    NPF_ATM_VC = 3
} NPF_MediaType_t;
3.1.5 Table Types
An Address Resolution Table is uniquely identified by a table handle which is defined as follows:

```c
typedef NPF_uint32_t NPF_IPv4UC_AddResTableHandle_t;
```

The IPv4 Unicast Forwarding API supports forwarding tables of two types, unified and discrete, which each have their own corresponding handle types. Other APIs, such as Interface Management and Packet Handler, depend on the IPv4 Unicast Forwarding API for handle definitions because they contain functions that refer to forwarding tables. The following Forwarding Table Handle represents a forwarding table (FIB) regardless of its mode. It is used in other APIs, so as not to expose the table’s type (unified or discrete) outside of the IPv4 Unicast Forwarding API. Also note that even though this `NPF_IPv4UC_FwdTableHandle_t` type is specified here, it is actually defined in the Software API Conventions, Revision 1, August 2002.

```c
typedef NPF_uint32_t NPF_IPv4UC_FwdTableHandle_t;
```

3.1.6 Return Codes
This section defines IPv4 Unicast Forwarding API return codes that are used for IPv4 forwarding and address resolution function calls. These codes are used for returns from asynchronous API function calls. The IPv4 range is defined in the NPF Software Implementation Agreement - Software API Conventions (Revision 1, August 2002) document.

```c
/*
 * Asynchronous error codes (returned in function callbacks)
 */

typedef NPF_uint32_t NPF_IPv4UC_ReturnCode_t;

#define IPV4_ERR(n) ((NPF_IPv4UC_ReturnCode_t) NPF_IPV4_BASE_ERR + (n))

#define NPF_IPV4UC_TABLE_FULL IPV4_ERR(0)
#define NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST IPV4_ERR(1)
#define NPF_IPV4UC_FUNCTION_NOT_SUPPORTED IPV4_ERR(2)
#define NPF_IPV4UC_INVALID_HANDLE IPV4_ERR(3)
#define NPF_IPV4UC_INSUFFICIENT_STORAGE IPV4_ERR(4)
#define NPF_IPV4UC_INVALID_MPLS_LSP_HANDLE IPV4_ERR(5)
```

Note that for optional functions, a return code having a value of `NPF_IPV4UC_FUNCTION_NOT_SUPPORTED` may be returned to the invoking application in two ways. This return code may be synchronously returned to the invoking application or it may be asynchronously returned via the completion callback. The added possibility of an immediate return code provides the application with a more efficient means of determining that a particular optional function is not supported by the implementation.

---

3 Currently, the NPF Interface Management API Implementation Agreement (Revision 1.0, August 2002) defines an API function call to associate an IPv4 FIB with one or more interfaces. This `NPF_ifIPv4FIBSet()` function call specifies an `if_FIB_Handle` parameter which is defined using an obsolete data type. In fact, this parameter should be defined using the `NPF_IPv4UC_FwdTableHandle_t` data type defined in this section. In addition, this same Implementation agreement defines a `NPF_IfIPv4_t` data structure that uses an obsolete data type. This structure should also be defined using the `NPF_IPv4UC_FwdTableHandle_t` data type defined in this section.

---
3.2 **Unified Mode Data Types**

3.2.1 **FIB Table Query Data Type**

This section defines the IPv4 specific control structures used for querying FIB table contents in unified implementations. The asynchronous callback data will contain one or more of the following NPF_IPv4UC_FibQueryResp_t structures. More than one structure is provided if multiple FIB table entries are queried at once.

- prefix – The prefix used to locate a particular entry in the FIB Table.
- nextHopArray – The set of one or more next hop definitions related to this prefix.

```c
/*
 * This structure contains the query results for a single FIB table entry.
 */
typedef struct {
    NPF_IPv4UC_Prefix_t prefix;
    NPF_IPv4UC_NextHopArray_t nextHopArray;
} NPF_IPv4UC_FibQueryResp_t;
```

3.2.2 **Table Types**

A FIB Table is uniquely identified within the scope of the IPv4 Unicast Forwarding API by a table handle which is defined as follows:

```c
typedef NPF_uint32_t NPF_IPv4UC_FibTableHandle_t;
```

Note that external to the IPv4 Unicast Forwarding API, a FIB table is uniquely identified by a table handle which is defined by the data type NPF_IPv4UC_FwdTableHandle_t. This specification could have forced API calls external to the IPv4 Unicast Forwarding API to specify a “FIB type” parameter and the internal FIB handle type. However, for a cleaner interface, a decision was made to use a single external handle type to identify a FIB, regardless of how the IPv4 function was structuring the information.

The following structure is used in the callback from the FIB Table handle creation function, to return two handles. The internal handle is used within the scope of the IPv4 unicast forwarding API and the external handle is used by other NPF API’s when referencing an IPv4 FIB. It is the responsibility of the application to maintain the mapping between these two handles, which refer to the same FIB.

```c
/*
 * Async Response struct for NPF_IPv4UC_FIBTableHandleCreate()
 */
typedef struct {
    NPF_IPv4UC_FwdTableHandle_t extHandle;
    NPF_IPv4UC_FibTableHandle_t intHandle;
} NPF_IPv4UC_FibCreateResp_t;
```
3.3 Discrete Mode Data Types

3.3.1 Prefix Table Query Data Type

This section defines the IPv4 specific control structures used for querying prefix table contents in discrete implementations. The asynchronous callback data will contain one or more of the following NPF_IPv4UC_PrefixQueryResp_t structures. More than one structure is provided if multiple prefix table entries are queried at once.

- prefix – The prefix used to locate a particular entry in the Prefix Table.
- nextHopIdentifier – The identifier of the next hop array in the Next Hop Table for this particular prefix.

```c
/*
 * This structure contains the query results for a single prefix table entry.
 */
typedef struct {
    NPF_IPv4UC_Prefix_t prefix;
    NPF_uint32_t  nextHopIdentifier;
} NPF_IPv4UC_PrefixQueryResp_t;
```

3.3.2 Next Hop Table Query Data Type

This section defines the IPv4 specific control structures used for querying next hop table contents in discrete implementations. The asynchronous callback data will contain one or more of the following NPF_IPv4UC_NextHopQueryResp_t structures. More than one structure is provided if multiple next hop table entries are queried at once.

- nextHopIdentifier – The next hop identifier used to locate a particular entry in the Next Hop Table.
- nextHopArray – The set of one or more next hop definitions related to this particular next hop identifier.

```c
/*
 * This structure contains the query results for a single next hop table entry.
 */
typedef struct {
    NPF_uint32    nextHopIdentifier;
    NPF_IPv4UC_NextHopArray_t nextHopArray;
} NPF_IPv4UC_NextHopQueryResp_t;
```

3.3.3 Table Types

A Prefix Table is uniquely identified within the scope of the IPv4 Unicast Forwarding API by a table handle, which is defined as follows:

```c
typedef NPF_uint32_t NPF_IPv4UC_PrefixTableHandle_t;
```
Note that external to the IPv4 Unicast Forwarding API, a prefix table is uniquely identified by a table handle which is defined by the data type NPF_IPv4UC_FwdTableHandle_t. This specification could have forced API calls external to the IPv4 Unicast Forwarding API to specify a “FIB type” parameter and the internal FIB handle type. However, for a cleaner interface, a decision was made to use a single external handle type to identify a FIB, regardless of how the IPv4 function was structuring the information.

The following structure is used in the callback from the Prefix Table handle creation function, to return two handles. The internal handle is used within the scope of the IPv4 Unicast forwarding API and the external handle is used by other NPF API’s when referencing an IPv4 FIB. It is the responsibility of the application to maintain the mapping between these two handles, which refer to the same FIB.

```c
/*
 * Async Response struct for NPF_IPv4UC_PrefixTableHandleCreate()
 */
typedef struct {
    NPF_IPv4UC_FwdTableHandle_t  extHandle;
    NPF_IPv4UC_PrefixTableHandle_t intHandle;
} NPF_IPv4UC_PfxCreateResp_t;
```

A Next Hop Table is uniquely identified by a table handle which is defined as follows:

```c
typedef NPF_uint32_t NPF(IPv4UC_NextHopTableHandle_t;
```

### 3.4 Data Structures for Completion Callbacks

This section defines the control structures needed for a Completion Callback, which provides the response information to the application which invoked an asynchronous function call. Although an asynchronous function call can request the execution of a single operation, many functions can also request the execution of multiple operations. For example, an NPF_IPv4UC_AddResEntryAdd function call may choose to add a single address resolution entry to the Address Resolution table, but it may also add multiple entries with a single function call invocation.

When a single operation is requested, a single completion callback will occur. However, when multiple operations are requested, not all of these requests may complete at the same time. The implementation MAY invoke the completion callback one or more times in order to provide responses for the total number of operations requested. For this reason, the callback data structure is designed to be flexible in how it provides status on these responses and it also allows the bundling of one or more responses into a single callback invocation.

Each completion callback provides the NPF_IPv4UC_CallbackData_t structure, whose members will have particular values depending on the invoking function, whether or not a single operation was requested and whether the operations were successful or not. The following sections provide details regarding the data structures involved in a completion callback.
3.4.1 Completion Callback Structures

The NPF_IPv4UC_CallbackData_t structure is provided as a parameter when the callback function is invoked. The basic definition of the fields is provided below, while more detailed descriptions follow.

- **type** – This field indicates which function invocation led to this response.
- **allOK** – This field and the numResp field provide a flexible means of providing information regarding the number of responses in this callback and their status. The specific details for these fields are provided below.
- **numResp** – This field and the allOK field provide a flexible means of providing information regarding the number of responses in this callback and their status. The specific details for these fields are provided below.
- **resp** – A pointer to an array of response elements or the NULL pointer. Each array element contains a return code, indicating the completion status of the request element, and possibly may contain other information specific to the type of request.

```c
typedef struct {
    NPF_IPv4UC_CallbackType_t   type;
    NPF_boolean_t         allOK;
    NPF_uint32_t          numResp;
    NPF_IPv4UC_AsyncResponse_t *resp;
} NPF_IPv4UC_CallbackData_t;
```

The following section provides detailed information regarding the content and meaning of the members in the NPF_IPv4UC_CallbackData_t structure. There are several possibilities to consider.

The application invokes a function requesting a single operation:

- If allOK = TRUE, then numResp = 0 and the “resp” pointer is NULL. This indicates the operation completed successfully and there is no other additional response data to return.
- If allOK = FALSE, then numResp = 1 and the “resp” pointer points to a response structure. If the returnCode field indicates NPF_NO_ERROR, the operation completed successfully and there is additional response data in the structure. Otherwise, the operation failed and the reason is indicated by the returnCode.

The application invokes a function requesting multiple operations:

- If all operations completed successfully at the same time and there is no additional response data to provide, then allOK = TRUE, numResp = 0 and the “resp” pointer is NULL.
- If all operations completed successfully at the same time, but there is additional response data to provide, then allOK = FALSE, numResp indicates the total number of requested operations and the “resp” pointer points to an array of response structures. The returnCode field will indicate NPF_NO_ERROR.
- If some operations completed, but not all, then:
  - allOK = FALSE, numResp = the number of request operations completed.
  - The “resp” pointer will point to an array of response structures, each one containing one element for each completed request. For operations that completed successfully, the returnCode field will indicate NPF_NO_ERROR and additional response data may be present, depending on the type of function invocation. For operations that failed, the reason is indicated by the returnCode field.

Callback function invocations are repeated in this fashion until all requests are complete. Responses are not repeated for request elements already indicated as complete in earlier callback function invocations.
The NPF_IPv4UC_AsyncResponse_t data structure contains a return code indicating an error or the success of a particular request operation. The structure may also contain other optional information that was requested by the operation or the information may assist in correlating the response to the corresponding request operation when multiple operations are requested by the application.

For IPv4 asynchronous function invocations that operate upon a particular table, it is the responsibility of the invoking application to associate the table handle with the subsequent asynchronous response. It is suggested that the “correlator”, supplied as an invocation parameter, be used for this purpose. For example, when invoking the NPF_IPv4UC_PrefixEntryAdd() function, the application can choose a correlator value that uniquely identifies, or points to, its own structures representing the forwarding table. This value returned by the implementation in each callback invocation can help the application know to which table the callback belongs. When the asynchronous NPF_IPv4UC_CallbackFunc() is called, the prefix table handle will be returned in its correlator parameter.

The type field in the NPF_IPv4UC_CallbackData_t structure identifies the asynchronous function call which has led to this callback, and therefore, the relevant member of the union.

One or more of the following structures may be provided to the callback function in the response array within the NPF_IPv4UC_CallbackData_t structure.

```c
typedef struct {
    NPF_IPv4UC_ReturnCode_t           returnCode;
    union {
        NPF_IPv4UC_PfxCreateResp_t      prefixTableHandles;
        NPF_IPv4UC_Prefix_t    prefix;
        NPF_IPv4UC_PrefixQueryResp_t    prefixQueryResult;
        NPF_uint32_t         nextHopTableHandle;
        NPF_uint32_t     unused;
    } u;
} NPF_IPv4UC_AsyncResponse_t;
```

The following structure defines the completion callback type values.

```c
typedef enum NPF_IPv4UC_CallbackType {
    NPF_IPV4UC_PREFIX_TABLE_HANDLE_CREATE        = 1,
    NPF_IPV4UC_PREFIX_TABLE_HANDLE_DELETE        = 2,
    NPF_IPV4UC_PREFIX_ENTRY_ADD                  = 3,
    NPF_IPV4UC_PREFIX_ENTRY_DELETE               = 4,
    NPF_IPV4UC_PREFIX_TABLE_FLUSH                = 5,
    NPF_IPV4UC_PREFIX_TABLE_ATTRIBUTE_QUERY      = 6,
    NPF_IPV4UC_PREFIX_ENTRY_QUERY        = 7,
    NPF_IPV4UC_PREFIX_NEXT_HOP_TABLE_BIND        = 8,
} NPF_IPv4UC_CallbackType;
```
### IPv4 Unicast Forwarding Task Group

### 3.5 Data Structures for Event Notification

The following sections detail the information related to IPv4 Unicast events. When an event notification routine is invoked, one of the parameters will be a structure of information related to one or more events.

#### 3.5.1 Event Notification Types

The event type indicates the type of event data in the union of event structures returned in NPF_IPv4UC_EventData_t.

```c
/*
 * This structure enumerates the events defined for IPv4
 * Unicast forwarding.
 */
typedef enum NPF_IPv4UC_Event {
    NPF_IPV4UC_PREFIX_TBL_MISS   =  1,
    NPF_IPV4UC_NEXT_HOP_TBL_MISS =  2,
    NPF_IPV4UC_ADD_RES_TBL_MISS  =  3,
    NPF_IPV4UC_FIB_PREFIX_MISS   =  4,
    NPF_IPV4UC_FWDTBL_REFRESH    =  5
} NPF_IPv4UC_Event_t;
```

#### 3.5.2 Event Notification Structures

This section describes the various events which MAY be implemented.

It is important to note that even if an implementation does not support any of these events, the implementation still needs to provide the register and deregister event function to enable interoperability.

Note that some of the event structures provide an internal handle identifying a FIB. It is the responsibility of the application to provide the mapping between these internal handles and any external FIB handles used in API invocations other than the IPv4 Unicast Forwarding API.

This structure defines all the possible event definitions for IPv4 Unicast. An event type field indicates which member of the union is relevant in the specific structure.

</tbody>
</table>
typedef struct {
    NPF_IPv4UC_Event_t             type;
    union {
        NPF_IPv4UC_PrefixTblMiss_t          prefixTblMiss;
        NPF_IPv4UC_NextHopTblMiss_t         nextHopTblMiss;
        NPF_IPv4UC_AddResTblMiss_t          addrResTblMiss;
        NPF_IPv4UC_FIB_PrefixMiss_t         fibPrefixMiss;
        NPF_IPv4UC_FwdTbl_Refresh_t         fwdTableRefreshRequest;
    } u;
} NPF_IPv4UC_EventData_t;

This event is triggered when the forwarding plane is unable to find a prefix table entry for a specific IP address. This event is optional.

typedef struct {
    NPF_IPv4UC_PrefixTableHandle_t    pfxTableHandle;
    NPF_IPv4Address_t       destIP_Address;
} NPF_IPv4UC_PrefixTblMiss_t;

This event is triggered when the forwarding plane is unable to find a next hop table entry for a specific next hop identifier. This event is optional.

define struct {
    NPF_IPv4UC_NextHopTableHandle_t    nextHopTableHandle;
    NPF_uint32_t        nextHopIdentifier;
} NPF_IPv4UC_NextHopTblMiss_t;

This event is triggered when the forwarding plane is unable to find a FIB table entry for a specific IP address. This event is optional.

typedef struct {
    NPF_IPv4UC_FibTableHandle_t       fibTableHandle;
    NPF_IPv4Address_t       destIP_Address;
} NPF_IPv4UC_FIB_PrefixMiss_t;
This event is triggered when the forwarding plane is unable to find an address resolution entry for a specific next hop. This event is optional.

```c
/*
 * This event data identifies the address resolution table and the next hop information that was not located during a lookup.
 */
typedef struct {
    NPF_IPv4UC_AddResTableHandle_t   addResTableHandle;
    NPF_ImplIfHandle_t    interfaceHandle;
    NPF_IPv4Address_t   IP_Address;
} NPF_IPv4UC_AddResTblMiss_t;
```

This event is triggered when the application or the IPv4 API implementation needs to be notified that a FIB needs to be refreshed on the forwarding plane. This event is optional.

```c
/*
 * This event data identifies the unified or discrete table handle identifying the FIB.
 */
typedef struct {
    NPF_IPv4UC_TableType_t            tableHandleType;
    union {
        NPF_IPv4UC_FibTableHandle_t     fibTableHandle;
        NPF_IPv4UC_PrefixTableHandle_t  prefixTableHandle;
    } u;
} NPF_IPv4UC_FwdTbl_Refresh_t;
```

```c
/*
 * This structure defines the enumerations for the table type used in the NPF_IPv4UC_FwdTbl_Refresh_t structure above.
 */
typedef enum NPF_IPv4UC_TableType {
    NPF_IPV4UC_FIB_TABLE        = 1,
    NPF_IPV4UC_PREFIX_TABLE     = 2
}NPF_IPv4UC_TableType_t;
```

This structure represents the data parameter provided when the event notification routine is invoked. It contains a count of events and an array of structures providing event specific information.

```c
/*
 * This structure is provided when the event notification handler is invoked. It specifies one or more IPv4 Unicast Forwarding events.
 */
typedef struct {
    NPF_uint32_t      numEvents;
    NPF_IPv4UC_EventData_t   *eventArray;
} NPF_IPv4UC_EventArray_t;
```
4 Function Calls

4.1 Completion Callback Function Calls
This callback function is for the application to register an asynchronous response handling routine to the IPv4Unicast API implementation. This callback function is intended to be implemented by the application, and to be registered to the IPv4 Unicast API implementation through the NPF_IPv4UC_Register function.

For more information regarding the design and usage of completion callbacks, please refer to Section 7, “Function Invocation Model, Events and Completion Callbacks”, of the Network Processing Forum Software API Conventions Implementation Agreement (Revision 1, August 2002).

4.1.1 NPF_IPv4UC_CallbackFunc

Syntax

typedef void (*NPF_IPv4UC_CallbackFunc_t) (  
    NPF_IN NPF_userContext_t         userContext,  
    NPF_IN NPF_correlator_t          correlator,  
    NPF_IN NPF_IPv4UC_CallbackData_t data);

Description

This function is a registered completion callback routine for handling IPv4 Unicast asynchronous responses.

This is a required function.

Input Arguments

• userContext - The context item that was supplied by the application when the completion callback routine was registered.

• correlator - The correlator item that was supplied by the application when the IPv4 Unicast API function call was invoked.

• data - The response information related to the particular IPv4 Unicast call, which is identified by the type field in the callback data.

Output Arguments

None

Return Values

None

4.2 Event Notification Function Calls

This event notification function is for the application to register an event handler routine to the IPv4Unicast API implementation. This handler function is intended to be implemented by the application, and to be registered to the IPv4 Unicast API implementation through the NPF_IPv4UC_EventRegister function.
4.2.1 NPF_IPv4UC_EventCallFunc_t

Syntax

```c
typedef void (*NPF_IPv4UC_EventCallFunc_t) (NPF_IN NPF_userContext_t userContext, NPF_IN NPF_IPv4UC_EventArray_t data);
```

Description

This function is a registered event notification routine for handling IPv4 Unicast events. This is a required function.

Input Arguments

- `userContext` - The context item that was supplied by the application when the event callback routine was registered.
- `data` – A structure containing an array of event data structures and a count to indicate how many events are present. Each of these NPF_IPv4UC_EventData_t members contains event specific information and a type field to identify the particular event.

Output Arguments

None

Return Values

None

4.3 Callback Registration/Deregistration Function Calls

This section defines the registration and de-registration functions used to install and remove an asynchronous response callback routine.

4.3.1 NPF_IPv4UC_Register

Syntax

```c
NPF_error_t NPF_IPv4UC_Register(NPF_IN NPF_userContext_t userContext, NPF_IN NPF_IPv4UC_CallbackFunc_t callbackFunc, NPF_OUT NPF_callbackHandle_t *callbackHandle);
```

Description

This function is used by an application to register its completion callback function for receiving asynchronous responses related to IPv4 Unicast API function calls. Applications MAY register multiple callback functions using this function. The callback function is identified by the pair of userContext and callbackFunc, and for each individual pair, a unique callbackHandle will be assigned for future reference.

Since the callback function is identified by both userContext and callbackFunc, duplicate registration of the same callback function with a different userContext is allowed. Also, the same userContext can be shared among different callback functions. Duplicate registration of the same userContext and callbackFunc pair has no effect, and will output a handle that is already assigned to the pair, and will return NPF_E_ALREADY_REGISTERED.

This is a required function.
Input Arguments

- **userContext** – A context item for uniquely identifying the context of the application registering the completion callback function. The exact value will be provided back to the registered completion callback function as its first parameter when it is called. Applications can assign any value to the userContext and the value is completely opaque to the IPv4Unicast API implementation.

- **callbackFunc** – The pointer to the completion callback function to be registered.

Output Arguments

- **callbackHandle** - A unique identifier assigned for the registered userContext and callbackFunc pair. This handle will be used by the application to specify which callback function to be called when invoking asynchronous NPF IPv4Unicast API functions. It will also be used when deregistering the userContext and callbackFunc pair.

Return Values

- **NPF_NO_ERROR** - The registration completed successfully.
- **NPF_E_BAD_CALLBACK_FUNCTION** – The callbackFunc is NULL, or otherwise invalid.
- **NPF_E_ALREADY_REGISTERED** – No new registration was made since the userContext and callbackFunc pair was already registered.

Notes

- This API function MUST be invoked by any application interested in receiving asynchronous responses for IPv4 Unicast API function calls.
- This function operates in a synchronous manner, providing a return value as listed above.

4.3.2 NPF_IPv4UC_Deregister

Syntax

```c
NPF_error_t NPF_IPv4UC_Deregister(
    NPF_IN NPF_callbackHandle_t callbackHandle);
```

Description

This function is used by an application to de-register a completion callback function, which was previously registered to handle asynchronous callbacks related to API function invocations. This is a required function.

Input Arguments

- **callbackHandle** - The unique identifier returned to the application when the completion callback routine was registered. It represents a unique user context and callback function pair.

Output Arguments

None

Return Values

- **NPF_NO_ERROR** - The de-registration completed successfully.
- **NPF_E_BAD_CALLBACK_HANDLE** – The de-registration did not complete successfully due to problems with the callback handle provided.
Notes

- This API function may be invoked by any application no longer interested in receiving asynchronous responses for IPv4 Unicast API function calls.
- This function operates in a synchronous manner, providing a return value as listed above.
- There may be a timing window where outstanding callbacks continue to be delivered to the callback routine after the de-registration function has been invoked. It is the implementation’s responsibility to guarantee that the callback function is not called after the deregister function has returned.

4.4 Event Registration/Deregistration Function Calls

This section defines the registration and de-registration functions used to install and remove an event handler routine

4.4.1 NPF_IPv4UC_EventRegister

Syntax

```c
NPF_error_t NPF_IPv4UC_EventRegister(
    NPF_IN NPF_userContext_t          userContext,
    NPF_IN NPF_IPv4UC_EventCallFunc_t eventCallFunc,
    NPF_OUT NPF_callbackHandle_t     *eventCallHandle);
```

Description

This function is used by an application to register its event handling routine for receiving notifications of IPv4 Unicast events. Applications MAY register multiple event handling routines using this function. The event handling routine is identified by the pair of userContext and eventCallFunc, and for each individual pair, a unique eventCallHandle will be assigned for future reference.

Since the event handling routine is identified by both userContext and eventCallFunc, duplicate registration of the same event handling routine with a different userContext is allowed. Also, the same userContext can be shared among different event handling routines. Duplicate registration of the same userContext and eventCallFunc pair has no effect, and will output a handle that is already assigned to the pair, and will return NPF_E_ALREADY_REGISTERED.

This is a required function.

Input Arguments

- userContext – A context item for uniquely identifying the context of the application registering the event handling routine. The exact value will be provided back to the registered event handling routine as its first parameter when it is called. Applications can assign any value to the userContext and the value is completely opaque to the IPv4Unicast API implementation
- eventCallFunc – The pointer to the event handling routine to be registered.

Output Arguments

- eventCallHandle - A unique identifier assigned for the registered userContext and eventCallFunc pair. This handle will be used when deregistering the userContext and eventCallFunc pair.

Return Values

- NPF_NO_ERROR - The registration completed successfully.
- NPF_E_BAD_CALLBACK_FUNCTION – The eventCallFunc is NULL, or otherwise invalid.
- NPF_E_CALLBACK_ALREADY_REGISTERED – No new registration was made since the userContext and eventCallFunc pair was already registered.
Notes

- This API function may be invoked by any application interested in receiving IPv4 Unicast events.
- This function operates in a synchronous manner, providing a return value as listed above.
- Even if an implementation does not support events, the implementation needs to implement this function to enable interoperability.

4.4.2 NPF_IPv4UC_EventDeregister

Syntax

```c
NPF_error_t NPF_IPv4UC_EventDeregister(
    NPF_IN NPF_callbackHandle_t eventCallHandle);
```

Description

This function is used by an application to de-register an event handler routine which was previously registered to receive notifications of IPv4 Unicast events. It represents a unique user context and event handling routine pair.

This is a required function.

Input Arguments

- eventCallHandle - The unique identifier returned to the application when the event callback routine was registered.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The de-registration completed successfully.
- NPF_E_BAD_CALLBACK_HANDLE – The de-registration did not complete successfully due to problems with the callback handle provided.

Notes

- This API function may be invoked by any application no longer interested in receiving IPv4 Unicast events.
- This function operates in a synchronous manner, providing a return value as listed above.
- There may be a timing window where outstanding events continue to be delivered to the event routine after the de-registration function has been invoked. It is the implementation’s responsibility to guarantee that the event handler function is not called after the deregister function has returned.
- Even if an implementation does not support events, the implementation needs to implement this function to enable interoperability.
4.5  Supported & Preferred Mode Query Function Calls

These function calls are used by applications to query an implementation about what table modes are supported and which are preferred for best performance.

4.5.1  NPF_IPv4UC_GetSupportedModes

Syntax

```c
NPF_IPv4UC_SupportedMode_t NPF_IPv4UC_GetSupportedModes();
```

Description

This function queries the supported table modes of an implementation.

Input Arguments

None

Output Arguments

None

Return Values

- NPF_IPV4UC_UNIFIED_ONLY – The table implementation only supports a unified table mode, and will return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED if the prefix and next hop table manipulation functions are used.
- NPF_IPV4UC_BOTH_SUPPORTED – The table implementation supports both a unified table mode and a discrete table mode.

Notes

None

Asynchronous Response

None

4.5.2  NPF_IPv4UC_GetPreferredMode

Syntax

```c
NPF_IPv4UC_PreferredMode_t NPF_IPv4UC_GetPreferredMode();
```

Description

This function queries the preferred table modes of an implementation. If the supported mode call indicates that only a unified mode is supported, then this function call will return NPF_IPV4UC_UNIFIED_PREFERRED. However, if the supported mode call indicates that both modes are supported, then this function call may return any one of the three return values listed below.

Input Arguments

None

Output Arguments

None
Return Values

- **NPF_IPV4UC_DISCRETE_PREFERRED** – The table implementation provides better performance when used with the discrete table APIs.
- **NPF_IPV4UC_UNIFIED_PREFERRED** – The table implementation provides better performance when used with the unified table APIs.
- **NPF_IPV4UC_NO_PREFERENCE** – The table implementation provides equally good or conditional performance when used with either API. Note that this value may only be returned if the supported mode call indicated both mode types are supported.

Notes

None

Asynchronous Response

None

4.6 Unified FIB Table Function Calls

This section specifies the functions defined to operate upon the unified mode FIB table.

4.6.1 NPF_IPv4UC_FibTableHandleCreate

Syntax

```c
NPF_error_t NPF_IPv4UC_FibTableHandleCreate(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting);
```

Description

This function creates internal and external handles for a FIB Table. The internal handle is used when calling IPv4 Unicast Forwarding API functions. The external handle is used when calling other functions in other APIs that need to refer to a forwarding table, regardless of whether it is managed in unified or discrete mode.

This is a required function.

Input Arguments

- `callbackHandle` - The unique identifier provided to the application when the completion callback routine was registered.
- `correlator` - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- `errorReporting` - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.

Output Arguments

None

Return Values

- **NPF_NO_ERROR** - The operation is in progress.
- **NPF_E_UNKNOWN** - The table handle creation did not complete successfully due to problems encountered when handling the input parameters.
- **NPF_E_BAD_CALLBACK_HANDLE** – The callback handle is not valid.
Notes
The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.

Asynchronous Response
An NPF_IPV4UC_FibCreateResp_t structure, containing both internal and external handles, will be returned along with a return code. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INSUFFICIENT_STORAGE - The operation failed due to lack of resources.

4.6.2 NPF_IPV4UC_FibTableHandleDelete
Syntax
NPF_error_t NPF_IPV4UC_FibTableHandleDelete(  NPF_IN NPF_callbackHandle_t           callbackHandle,  NPF_IN NPF_correlator_t               correlator,  NPF_IN NPF_errorReporting_t           errorReporting,  NPF_IN NPF_IPV4UC_FibTableHandle_t    tableHandle);  

Description
This function deletes a handle for a FIB Table. Subsequent use of the deleted handle in an API function call will result in an NPF_IPV4UC_INVALID_HANDLE error.
This is a required function.

Input Arguments
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- tableHandle - The FIB table handle to delete.

Output Arguments
None

Return Values
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table handle deletion did not complete successfully due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.

Notes
None

Asynchronous Response
A return code will be returned asynchronously. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
4.6.3 NPF_IPv4UC_FibEntryAdd

Syntax

```c
NPF_error_t NPF_IPv4UC_FibEntryAdd(
    NPF_IN NPF_callbackHandle_t    callbackHandle,
    NPF_IN NPF_correlator_t        correlator,
    NPF_IN NPF_errorReporting_t    errorReporting,
    NPF_IN NPF_IPv4UC_FibTableHandle_t  tableHandle,
    NPF_IN NPF_uint32_t    numEntries,
    NPF_IN NPF_IPv4UC_Prefix_t  *prefixArray,
    NPF_IN NPF_IPv4UC_NextHopArray_t *nextHopArrays);
```

Description

This function may be used to insert one or more entries into a FIB table. The prefixArray and nextHopArrays fields point to arrays of size numEntries, where each element is positionally related. If no table entry exists for each destination IPv4 address and length indicated in the prefixArray, then the prefix and next hop array information is added to create a new entry in the specified table. If a table entry already exists, then the next hop array is replaced with the information specified in the associated element of the nextHopArrays array.

This is a required function.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- tableHandle - FIB table identifier.
- numEntries – The number of elements in the prefixArray and the nextHopArrays. Each of these arrays has the same number of elements and they are positionally related.
- prefixArray – Pointer to the array of prefixes to add.
- nextHopArrays – Pointer to an array of NPF_IPv4UC_NextHopArray_t structures, which are associated with the prefixes. Each NPF_IPv4UC_NextHopArray_t structure contains a count plus one or more next hop.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not added to the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not added to the table because the callback handle was invalid.
Notes
When determining whether an entry is already present in the FIB, only the IPv4 address and prefix length are considered.

Asynchronous Response
There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_Prefix_t structure will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_INSUFFICIENT_STORAGE - The operation failed due to lack of resources.
- NPF_IPV4UC_INVALID_MPLS_LSP_HANDLE – The operation failed due to an invalid LSP handle at the prefix specified in the associated callback structure (see below).

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and prefix length.

An NPF_IPV4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPV4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.

4.6.4 NPF_IPV4UC_FibEntryDelete

Syntax

```c
NPF_error_t NPF_IPV4UC_FibEntryDelete(
    NPF_IN NPF_callbackHandle_t    callbackHandle,
    NPF_IN NPF_correlator_t        correlator,
    NPF_IN NPF_errorReporting_t    errorReporting,
    NPF_IN NPF_IPV4UC_FibTableHandle_t  tableHandle,
    NPF_IN NPF_uint32_t    numEntries,
    NPF_IN NPF_IPV4UC_Prefix_t  *prefixArray);
```

Description
All entries in the designated FIB table that match those found in the prefixArray will be removed. This is a required function.
Input Arguments
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- tableHandle - FIB table identifier.
- numEntries – The number of elements in the prefixArray.
- prefixArray – A pointer to an array of prefixes, one for each FIB table entry to be deleted.

Output Arguments
None

Return Values
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not deleted from the table because the callback handle was invalid.

Notes
When determining whether an entry is already present in the FIB table, only the IPv4 address and prefix length are considered.

Asynchronous Response
There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_Prefix_t structure will be returned along with a return code. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST - The operation did not complete successfully since the specified entry was not found.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the corresponding IP address and prefix length.
An NPF_IPv4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPv4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.
If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.
It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.
4.6.5 NPF_IPv4UC_FibTableFlush

Syntax

```c
NPF_error_t NPF_IPv4UC_FibTableFlush(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting,
    NPF_IN NPF_IPv4UC_FibTableHandle_t tableHandle);
```

Description

All entries in the designated FIB table will be removed and the designated FIB will be left empty. This is a required function.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- tableHandle - FIB table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not deleted from the table because the callback handle was invalid.

Notes

This operation removes all entries from the specified FIB table, but does not destroy that FIB table. If a FIB entry is removed, a reference to the removed entry by the forwarding plane MAY generate an NPF_IPV4UC_FIB_PREFIX_MISS event.

Asynchronous Response

A return code will be returned asynchronously. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
4.6.6 NPF_IPv4UC_FibTableAttributeQuery

Syntax

```c
NPF_error_t NPF_IPv4UC_FibTableAttributeQuery(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting,
    NPF_IN NPF_IPv4UC_FibTableHandle_t tableHandle);
```

Description

This call will provide information about the characteristics of the specified FIB table. Currently, the attributes available are:

- An estimate of how many free entries are in this table.

This is an optional function. Implementations that do not support attribute queries MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation. The only valid error reporting for this method is NPF_REPORT_ALL.
- tableHandle – FIB table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table was not queried due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The table was not queried because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability is not supported by this implementation.

Notes

Applications may use this query API function to obtain information useful in maintaining the FIB table. For example, prior to inserting any entries into the FIB table, an RTM might query the available free space of the FIB table and, therefore, be able to know when it cannot add any more entries to the table.

The implementation SHOULD be conservative in what it returns. In other words, the value should be the amount of free space under the worst-case conditions, so that the application can be assured that at least this many “Add” requests will succeed.
The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.

**Asynchronous Response**

A return code will be returned asynchronously along with an approximation of the number of free entries left in the FIB table. The tableSpaceRemaining field in the NPF_IPv4UC_AsyncResponse_t struct will be set. Possible return codes are:

- **NPF_NO_ERROR** - The operation completed successfully.
- **NPF_IPV4UC_INVALID_HANDLE** - The operation did not complete successfully due to problems with the table handle.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – The attribute query capability is not supported by this implementation.

### 4.6.7 NPF_IPv4UC_FibEntryQuery

**Syntax**

```c
NPF_error_t NPF_IPv4UC_FibEntryQuery(
    NPF_IN NPF_callbackHandle_t    callbackHandle,
    NPF_IN NPF_correlator_t        correlator,
    NPF_IN NPF_errorReporting_t    errorReporting,
    NPF_IN NPF_IPv4UC_FibTableHandle_t  tableHandle,
    NPF_IN NPF_uint32_t    numEntries,
    NPF_IN NPF_IPv4UC_Prefix_t  *prefixArray);
```

**Description**

This function call is used to query one or more FIB entries in the FIB table. If the entries exist, the content of the entries are returned in the completion callback.

This is an optional function. Implementations that do not support entry queries MUST implement a stub of this function and MUST either immediately return

NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return

NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

**Input Arguments**

- `callbackHandle` - The unique identifier provided to the application when the completion callback routine was registered.
- `correlator` - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- `errorReporting` - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- `tableHandle` - FIB table identifier.
- `numEntries` – The number of elements in the `prefixArray`.
- `prefixArray` – A pointer to an array of prefixes to query. Only the IP address and prefix length are considered in the key.

**Output Arguments**

- None
Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not queried due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not queried because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The query capability is not supported by this implementation.

Notes

None

Asynchronous Response

There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_FibQueryResp_t structure will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST - The operation did not complete successfully since the specified entry was not found.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The entry query capability is not supported by this implementation.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and prefix length.

An NPF_IPv4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPv4UC_AsyncResponse_t structures will also be returned. Because this function call will always return information that was requested, if all of the elements in the request array completed successfully and there is no additional data to return, the callback will return an allOK value of NPF_FALSE, a numResp value equal to the number of responses, and the array pointer pointing to the responses.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.
### 4.7 Discrete Prefix Table Function Calls

This section specifies the functions defined to operate upon the discrete mode prefix table.

#### 4.7.1 NPF_IPv4UC_PrefixTableHandleCreate

**Syntax**

```c
NPF_error_t NPF_IPv4UC_PrefixTableHandleCreate(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting);
```

**Description**

This function creates internal and external handles for a Prefix Table. The internal handle is used when calling IPv4 Unicast Forwarding API functions. The external handle is used when calling other functions in other APIs that need to refer to a forwarding table, regardless of whether it is managed in unified or discrete mode.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

**Input Arguments**

- `callbackHandle` - The unique identifier provided to the application when the completion callback routine was registered.
- `correlator` - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- `errorReporting` - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.

**Output Arguments**

None

**Return Values**

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table handle creation did not complete successfully due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

**Notes**

The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.

**Asynchronous Response**

An `NPF_IPv4UC_PfxCreateResp_t` structure, containing both internal and external handles, will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR – The operation completed successfully.
- NPF_IPV4UC_INSUFFICIENT_STORAGE – The operation failed due to lack of resources.
• NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

4.7.2 NPF_IPv4UC_PrefixTableHandleDelete

Syntax

NPF_error_t NPF_IPv4UC_PrefixTableHandleDelete(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPv4UC_PrefixTableHandle_t tableHandle);

Description

This function deletes a handle for a Prefix Table. Subsequent use of the deleted handle in an API function call will result in an NPF_IPV4UC_INVALID_HANDLE error.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

• callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
• correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
• errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
• tableHandle - The prefix table handle to delete.

Output Arguments

None

Return Values

• NPF_NO_ERROR - The operation is in progress.
• NPF_E_UNKNOWN - The table handle deletion did not complete successfully due to problems encountered when handling the input parameters.
• NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.
• NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

Notes

None

Asynchronous Response

A return code will be returned asynchronously. Possible return codes are:

• NPF_NO_ERROR - The operation completed successfully.
• NPF_IPV4UC_INVALID_HANDLE – The operation did not complete successfully due to problems with the table handle.
• NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.
4.7.3 NPF_IPv4UC_PrefixEntryAdd

Syntax

```c
NPF_error_t NPF_IPv4UC_PrefixEntryAdd(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPv4UC_PrefixTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t                   numEntries,
    NPF_IN NPF_IPv4UC_Prefix_t        *prefixArray,
    NPF_IN NPF_uint32_t    *nextHopIdArray);
```

Description

This function may be used to insert one or more entries into a prefix table. The prefixArray and nextHopIdArray fields point to arrays of size numEntries, where each element is positionally related. If no table entry exists for each destination IPv4 address and length indicated in the prefixArray, then the prefix and next hop identifier information is added to create a new entry in the specified table. If a table entry already exists, then the next hop identifier is replaced with the information specified in the associated element of the nextHopIdArray.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- *callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- *correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- *errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- *tableHandle - Prefix table identifier.
- *numEntries – The number of elements in the prefixArray and the nextHopIdArray. Each of these arrays has the same number of elements and they are positionally related.
- *prefixArray - Pointer to the array of prefixes to add.
- *nextHopIdArray – Pointer to the array of next hop identifiers associated with the prefixes.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not added to the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not added to the table because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.
Notes
When determining whether an entry is already present in the prefix table, only the IPv4 address and prefix length are considered.

Asynchronous Response
There may be multiple asynchronous callbacks to this request. An `NPF_IPV4UC_Prefix_t` structure will be returned along with a return code. Possible return codes are:

- `NPF_NO_ERROR` - The operation completed successfully.
- `NPF_IPV4UC_INVALID_HANDLE` - The operation did not complete successfully due to problems with the table handle.
- `NPF_IPV4UC_INSUFFICIENT_STORAGE` - The operation failed due to lack of resources.
- `NPF_IPV4UC_FUNCTION_NOT_SUPPORTED` - Discrete table operations are not supported by this implementation.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and prefix length.

An `NPF_IPV4UC_CallbackData_t` will be returned with each callback. As part of that structure, an array of `NPF_IPV4UC_AsyncResponse_t` structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an `allOK` value of `NPF_TRUE`, a `numResp` value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, `allOK` will be `NPF_FALSE`, the `numResp` field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.

4.7.4 NPF_IPV4UC_PrefixEntryDelete

Syntax

```c
NPF_error_t NPF_IPV4UC_PrefixEntryDelete(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPV4UC_PrefixTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t                   numEntries,
    NPF_IN NPF_IPV4UC_Prefix_t        *prefixArray);
```

Description

This function may be used to remove one or more entries from a prefix table. If a prefix table entry exists as indicated by the destination IPv4 address and prefix length in an element contained in the `prefixArray`, then that entry will be removed from the specified table.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return `NPF_IPV4UC_FUNCTION_NOT_SUPPORTED` when called or MUST return `NPF_IPV4UC_FUNCTION_NOT_SUPPORTED` in the returnCode field of the asynchronous callback structure.
Input Arguments
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle - Prefix table identifier.
- numEntries – The number of elements in the prefixArray.
- prefixArray - A pointer to an array of prefixes, one for each prefix table entry to be deleted.

Output Arguments
None

Return Values
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not deleted from the table because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

Notes
When determining whether an entry is already present in the prefix table, only the IPv4 address and prefix length are considered.

Asynchronous Response
There may be multiple asynchronous callbacks to this request. An NPF_IPV4UC_Prefix_t structure will be returned along with a return code. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST – The operation did not complete successfully since the specified entry was not found.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and prefix length.

An NPF_IPV4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPV4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.
If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function calls.

4.7.5 NPF_IPv4UC_PrefixTableFlush

Syntax

NPF_error_t NPF_IPv4UC_PrefixTableFlush(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPv4UC_PrefixTableHandle_t tableHandle);

Description

All entries in the designated prefix table will be removed and the designated table will be left empty.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle - Prefix table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The prefix table was not flushed due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The prefix table was not flushed because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

Notes

This operation removes all entries from the specified table, but does not destroy that table.

If a prefix table entry is removed, a reference to the removed entry by the forwarding plane MAY generate an NPF_IPV4UC_PREFIX_TBL_MISS event.
Asynchronous Response
A return code will be returned asynchronously. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

4.7.6 NPF_IPv4UC_PrefixTableAttributeQuery

Syntax

\[
\text{NPF_error_t NPF_IPv4UC_PrefixTableAttributeQuery(}
\text{NPF_IN NPF_callbackHandle_t callbackHandle,}
\text{NPF_IN NPF_correlator_t correlator,}
\text{NPF_IN NPF_errorReporting_t errorReporting,}
\text{NPF_IN NPF_IPv4UC_PrefixTableHandle_t tableHandle);}
\]

Description

This call will provide information about the characteristics of the specified prefix table. Currently, the attributes available are:

- An estimate of how many free entries are in this table.

This is an optional function. Implementations that do not support queries or that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation. The only valid error reporting for this call is NPF_REPORT_ALL.
- tableHandle - Prefix table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table was not queried due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The table was not queried because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability or discrete table operations are not supported by this implementation.
Notes

Applications may use this query API function to obtain information useful in maintaining the prefix table. For example, prior to inserting any prefix entries into the prefix table, an RTM might query the available free space of the prefix table and, therefore, be able to know when it cannot add any more entries to the table.

The implementation SHOULD be conservative in what it returns. In other words, the value should be the amount of free space under the worst-case conditions, so that the application can be assured that at least this many “Add” requests will succeed.

The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.

Asynchronous Response

A return code will be returned asynchronously along with an approximation of the number of free entries left in the prefix table. The tableSpaceRemaining field in the NPF_IPv4UC_AsyncResponse_t struct will be set. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability is not supported or discrete table operations are not supported by this implementation.

4.7.7 NPF_IPV4UC_PrefixEntryQuery

Syntax

```c
NPF_error_t NPF_IPV4UC_PrefixEntryQuery(
    NPF_IN NPF_callbackHandle_t          callbackHandle,
    NPF_IN NPF_correlator_t              correlator,
    NPF_IN NPF_errorReporting_t          errorReporting,
    NPF_IN NPF_IPV4UCPrefixTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t    numEntries,
    NPF_IN NPF_IPV4UC_Prefix_t          *prefixArray);
```

Description

This function call is used to query one or more prefix entries in the prefix table. If the entries exist, the content of the entries are returned in the completion callback.

This is an optional function. Implementations that do not support queries or that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API invocation.
- tableHandle - Prefix table identifier.
- **numEntries** – The number of elements in the prefixArray.
- **prefixArray** - Pointer to the array of prefixes to query. Only the address and prefix length are considered in the key.

**Output Arguments**

None

**Return Values**

- **NPF_NO_ERROR** - The operation is in progress.
- **NPF_E_UNKNOWN** - The entries were not queried due to problems encountered when handling the input parameters.
- **NPF_E_BAD_CALLBACK_HANDLE** - The entries were not queried because the callback handle was invalid.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – The entry query capability or discrete table operations are not supported by this implementation.

**Asynchronous Response**

There may be multiple asynchronous callbacks to this request. An **NPF_IPV4UC_PrefixQueryResp_t** structure will be returned along with a return code. Possible return codes are:

- **NPF_NO_ERROR** - The operation completed successfully.
- **NPF_IPV4UC_INVALID_HANDLE** - The operation did not complete successfully due to problems with the table handle.
- **NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST** - The operation did not complete successfully since the specified entry was not found.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – The entry query capability is not supported or discrete table operations are not supported by this implementation.

The response array returned in the call back may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and prefix length.

An **NPF_IPV4UC_CallbackData_t** will be returned with each callback. As part of that structure, an array of **NPF_IPV4UC_AsyncResponse_t** structures will also be returned. Because this function call will always return information that was requested, if all of the elements in the request array completed successfully and there is no additional data to return, the callback will return an allOK value of **NPF_FALSE**, a numResp value equal to the number of responses, and the array pointer pointing to the responses.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be **NPF_FALSE**, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function calls.
4.7.8  NPF_IPv4UC_PrefixNextHopTableBind

Syntax

NPF_error_t NPF_IPv4UC_PrefixNextHopTableBind(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting,
    NPF_IN NPF_IPv4UC_PrefixTableHandle_t prefixTableHandle,
    NPF_IN NPF_IPv4UC_NextHopTableHandle_t nextHopTableHandle);

Description

This function makes an association between a Prefix Table and a Next Hop Table. It designates the
Next Hop Table whose entries are to be used when a particular Prefix Table is referenced. If the
Prefix Table is already associated with another Next Hop Table, that association is replaced by the
new Next Hop Table. If the Next Hop Table is already associated with a different Prefix Table, the
new Prefix Table is added to the set of Prefix Tables that share this Next Hop Table. Thus the
possible relationships of Prefix Table to Next Hop Table are one-to-one and many-to-one, but never
one-to-many.

This is an optional function. Implementations that do not support a discrete table mode MUST
implement a stub of this function and MUST either immediately return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous
callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback
  routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous
  completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous
  completion callback for this API function call.
- prefixTableHandle - The prefix table identifier.
- nextHopTableHandle - The next hop table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table binding did not complete successfully due to problems
  encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported
  by this implementation.

Notes

None
Asynchronous Response

A return code will be returned asynchronously. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE – The operation did not complete successfully due to problems with one of the table handles.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

4.8 Discrete Next Hop Table Function Calls

This section specifies the functions defined to operate upon the discrete mode next hop table.

4.8.1 NPF_IPv4UC_NextHopTableHandleCreate

Syntax

NPF_error_t NPF_IPv4UC_NextHopTableHandleCreate(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t     correlator,
    NPF_IN NPF_errorReporting_t errorReporting);

Description

This function creates a handle for a Next Hop Table.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator  - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting  - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table handle creation did not complete successfully due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

Notes

The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.
Asynchronous Response

A next hop table handle will be returned along with a return code. Possible return codes are:

- **NPF_NO_ERROR** - The operation completed successfully.
- **NPF_IPV4UC_INSUFFICIENT_STORAGE** - The operation failed due to lack of resources.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – Discrete table operations are not supported by this implementation.

4.8.2 **NPF_IPV4UC_NextHopTableHandleDelete**

**Syntax**

```c
NPF_error_t NPF_IPV4UC_NextHopTableHandleDelete(
    NPF_IN NPF_callbackHandle_t        callbackHandle,
    NPF_IN NPF_correlator_t            correlator,
    NPF_IN NPF_errorReporting_t        errorReporting,
    NPF_IN NPF_IPV4UC_NextHopTableHandle_t tableHandle);
```

**Description**

This function deletes a handle for a Next Hop Table. Subsequent use of the deleted handle in an API function call will result in an NPF_IPV4UC_INVALID_HANDLE error.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

**Input Arguments**

- **callbackHandle** - The unique identifier provided to the application when the completion callback routine was registered.
- **correlator** - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- **errorReporting** - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- **tableHandle** - The next hop table handle to delete.

**Output Arguments**

None

**Return Values**

- **NPF_NO_ERROR** - The operation is in progress.
- **NPF_E_UNKNOWN** - The table handle deletion did not complete successfully due to problems encountered when handling the input parameters.
- **NPF_E_BAD_CALLBACK_HANDLE** – The callback handle is not valid.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – Discrete table operations are not supported by this implementation.

**Notes**

None
Asynchronous Response

A return code will be returned asynchronously. Possible return codes are:

- **NPF_NO_ERROR** - The operation completed successfully.
- **NPF_IPV4UC_INVALID_HANDLE** - The operation did not complete successfully due to problems with the table handle.
- **NPF_IPV4UC_FUNCTION_NOT_SUPPORTED** – Discrete table operations are not supported by this implementation.

4.8.3 **NPF_IPV4UC_NextHopEntryAdd**

**Syntax**

```c
NPF_error_t NPF_IPV4UC_NextHopEntryAdd(
    NPF_IN NPF_callbackHandle_t            callbackHandle,
    NPF_IN NPF_correlator_t                correlator,
    NPF_IN NPF_errorReporting_t            errorReporting,
    NPF_IN NPF_IPV4UC_NextHopTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t                    numEntries,
    NPF_IN NPF_ipv4UC_NextHopIdArray_t     *nextHopIdArray,
    NPF_IN NPF_ipv4UC_NextHopArray_t       *nextHopArrays);
```

**Description**

This function may be used to insert one or more entries into a next hop table. The nextHopIdArray and nextHopArrays fields point to arrays of size numEntries, where each element is positionally related.

If no table entry exists for each next hop identifier indicated in the nextHopIdArray, then the next hop identifier and next hop array information is added to create a new entry in the specified table.

If a table entry already exists, then the next hop array is replaced with the information specified in the associated element of the nextHopArrays array.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

**Input Arguments**

- **callbackHandle** - The unique identifier provided to the application when the completion callback routine was registered.
- **correlator** - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- **errorReporting** - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- **tableHandle** – Next Hop Table identifier.
- **numEntries** – The number of elements in the nextHopIdArray and the nextHopArrays. Each of these arrays has the same number of elements and they are positionally related.
- **nextHopIdArray** – Pointer to an array of next hop identifiers.
- **nextHopArrays** - Pointer to an array of NPF_IPV4UC_NextHopArray_t structures, which are associated with the next hop identifiers. Each NPF_IPV4UC_NextHopArray_t structure contains a count plus one or more next hop definitions.
**Output Arguments**
None

**Return Values**
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not added to the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not added to the table because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

**Notes**
None

**Asynchronous Response**
There may be multiple asynchronous callbacks to this request. The NextHop Identifier will be returned along with a return code. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_INSUFFICIENT_STORAGE - The operation failed due to lack of resources.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.
- NPF_IPV4UC_INVALID_MPLS_LSP_HANDLE - The operation failed due to an invalid LSP handle at the Next Hop Identifier specified in the associated callback structure (see below).

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the Next Hop Identifier value. An NPF_IPV4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPV4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.
4.8.4 NPF_IPv4UC_NextHopEntryDelete

Syntax

```c
NPF_error_t NPF_IPv4UC_NextHopEntryDelete(
    NPF_IN NPF_callbackHandle_t            callbackHandle,
    NPF_IN NPF_correlator_t                correlator,
    NPF_IN NPF_errorReporting_t            errorReporting,
    NPF_IN NPF_IPv4UC_NextHopTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t                    numEntries,
    NPF_IN NPF_uint32_t                   *nextHopIdArray);
```

Description

This function deletes one or more Next Hop Entries. If a Next Hop Entry exists, that entry will be removed from the specified table.

If a Next Hop Entry is removed, a reference to the removed entry by the forwarding plane MAY generate an NPF_IPV4UC_NEXT_HOP_TBL_MISS event.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle – Next Hop Table identifier.
- numEntries – The number of elements in the nextHopIdArray.
- nextHopIdArray – A pointer to an array of Next Hop Identifier values, one for each next hop table entry to be deleted.

Output Arguments

- None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not deleted from the table because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.
Asynchronous Response

There may be multiple asynchronous callbacks to this request. The NextHop Identifier will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST - The operation did not complete successfully since the specified entry was not found.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the next hop identifier value.

An NPF_IPv4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPv4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.

4.8.5 NPF_IPV4UC_NextHopTableFlush

Syntax

\[
\text{NPF_error_t NPF_IPV4UC_NextHopTableFlush(} \\
\text{NPF_IN NPF_callbackHandle_t callbackHandle,} \\
\text{NPF_IN NPF_correlator_t correlator,} \\
\text{NPF_IN NPF_errorReporting_t errorReporting,} \\
\text{NPF_IN NPF_IPV4UC_NextHopTableHandle_t tableHandle);}
\]

Description

All entries in the designated next hop table will be removed and the designated table will be left empty.

This is an optional function. Implementations that do not support a discrete table mode MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.
Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle – Next Hop Table identifier.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table was not flushed due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The table was not flushed because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

Notes

This operation removes all entries from the specified table, but does not destroy that table. If a Next Hop Entry is removed, a reference to the removed entry by the forwarding plane MAY generate an NPF_IPV4UC_NEXT_HOP_TBL_MISS event.

Asynchronous Response

A return code will be returned asynchronously. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – Discrete table operations are not supported by this implementation.

4.8.6 NPF_IPV4UC_NextHopTableAttributeQuery

Syntax

```c
NPF_error_t NPF_IPV4UC_NextHopTableAttributeQuery(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting,
    NPF_IN NPF_IPV4UC_NextHopTableHandle_t tableHandle);
```

Description

This call will provide information about the characteristics of the specified Next Hop Table. Currently, the attributes available are:

- An estimate of how many free entries are in this table.
This is an optional function. Implementations that do not support queries or that do not support a
discrete table mode MUST implement a stub of this function and MUST either immediately return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous
callback structure.

**Input Arguments**

- callbackHandle - The unique identifier provided to the application when the completion callback
  routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous
  completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous
  completion callback for this API function invocation. The only valid reporting level is
  NPF_REPORT_ALL.
- tableHandle – The Next Hop Table identifier.

**Output Arguments**

None

**Return Values**

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table was not queried due to problems encountered when handling
  the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The table was not queried because the callback handle
  was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability or discrete
  table operations are not supported by this implementation.

**Notes**

Applications may use this query API function to obtain information useful in maintaining the Next
Hop Table. For example, prior to inserting any next hop entries into the next hop table, an RTM
might query the available free space of the Next Hop Table and, therefore, be able to know when it
cannot add any more entries to the table.

The implementation SHOULD be conservative in what it returns. In other words, the value should be
the amount of free space under the worst-case conditions, so that the application can be assured that at
least this many “Add” requests will succeed.

The errorReporting parameter, included for the sake of consistency, is ignored. This function
 generates an asynchronous response, regardless of the value given in the errorReporting parameter.

**Asynchronous Response**

A return code will be returned asynchronously along with an approximation of the number of free
entries left in the Next Hop Table. The tableSpaceRemaining field in the
NPF_IPV4UC_AsyncResponse_t struct will be set. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to
  problems with the table handle.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability is not
  supported or discrete table operations are not supported by this implementation.
4.8.7 NPF_IPv4UC_NextHopEntryQuery

Syntax

NPF_error_t NPF_IPv4UC_NextHopEntryQuery(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPv4UC_NextHopTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t      numEntries,
    NPF_IN NPF_uint32_t     *nextHopIdArray);

Description

This function call is used to query one or more next hop entries in the next hop table. If the entries
exist, the content of the entries are returned in the completion callback.

This is an optional function. Implementations that do not support queries or that do not support a
discrete table mode MUST implement a stub of this function and MUST either immediately return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return
NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous
callback structure.

Input Arguments

• callbackHandle - The unique identifier provided to the application when the completion callback
  routine was registered.
• correlator - A unique application invocation value that will be supplied to the asynchronous
  completion callback routine.
• errorReporting - An indication of whether the application desires to receive an asynchronous
  completion callback for this API invocation.
• tableHandle – Next hop table identifier.
• numEntries  – The number of elements in the nextHopIdArray.
• nextHopIdArray - Pointer to the array of next hop identifiers to query. Only the next hop
  identifier is considered in the key.

Output Arguments

None

Return Values

• NPF_NO_ERROR - The operation is in progress.
• NPF_E_UNKNOWN - The entries were not queried due to problems encountered when handling
  the input parameters.
• NPF_E_BAD_CALLBACK_HANDLE - The entries were not queried because the callback
  handle was invalid.
• NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The query capability or discrete table
  operations are not supported by this implementation.
Asynchronous Response

There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_NextHopQueryResp_t structure will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST - The operation did not complete successfully since the specified entry was not found.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The entry query capability is not supported or discrete table operations are not supported by this implementation.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the next hop identifier value.

An NPF_IPv4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPv4UC_AsyncResponse_t structures will also be returned. Because this function call will always return information that was requested, if all of the elements in the request array completed successfully and there is no additional data to return, the callback will return an allOK value of NPF_FALSE, a numResp value equal to the number of responses, and the array pointer pointing to the responses.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.

4.9 Address Resolution Function Calls

This section specifies the functions defined to operate upon the address resolution table. These functions are intended to be used in either unified or discrete modes.

4.9.1 NPF_IPv4UC_AddResTableHandleCreate

Syntax

NPF_error_t NPF_IPv4UC_AddResTableHandleCreate(
    NPF_IN NPF_callbackHandle_t callbackHandle,
    NPF_IN NPF_correlator_t correlator,
    NPF_IN NPF_errorReporting_t errorReporting);

Description

This function creates a handle for an Address Resolution Table.

This is a required function.
Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.

Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table handle creation did not complete successfully due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.

Notes

The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.

Asynchronous Response

An address resolution table handle will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INSUFFICIENT_STORAGE - The operation failed due to lack of resources.

4.9.2 NPF_IPV4UC_AddResTableHandleDelete

Syntax

```c
NPF_error_t NPF_IPV4UC_AddResTableHandleDelete(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPV4UC_AddResTableHandle_t tableHandle);
```

Description

This function deletes a handle for an Address Resolution Table. Subsequent use of the deleted handle in an API function call will result in an NPF_IPV4UC_INVALID_HANDLE error.

This is a required function.

Input Arguments

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- tableHandle - The address resolution table handle to delete.
Output Arguments
None

Return Values
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table handle deletion did not complete successfully due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The callback handle is not valid.

Notes
None

Asynchronous Response
A return code will be returned asynchronously. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.

4.9.3 NPF_IPV4UC_AddResEntryAdd

Syntax
NPF_error_t NPF_IPV4UC_AddResEntryAdd(
    NPF_IN NPF_callbackHandle_t             callbackHandle,
    NPF_IN NPF_correlator_t                 correlator,
    NPF_IN NPF_errorReporting_t             errorReporting,
    NPF_IN NPF_IPV4UC_AddResTableHandle_t   tableHandle,
    NPF_IN NPF_uint32_t                     numEntries,
    NPF_IN NPF_IPV4UC_AddResEntry_t         *entryArray);

Description
This function may be used to insert one or more entries into an address resolution table. The entryArray field points to an array of size numEntries, where each element is an address resolution entry to add.

If no table entry exists for the IP address and interface pair supplied in the entryArray, then the address resolution entry information is added to create a new entry in the specified table.

If a table entry already exists, then it is replaced with the information specified in the entryArray.

This is a required function.

Input Arguments
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle – Address Resolution table identifier.
- numEntries – The number of elements in the entryArray.
- entryArray - Pointer to an array of NPF_IPV4UC_AddResEntry_t structures. Each structure has an IP address, logical interface handle and a media specific address.
Output Arguments

None

Return Values

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not added due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The entries were not added to the table because the callback handle was invalid.

Asynchronous Response

There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_AddResKey_t structure will be returned along with a return code. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_INSUFFICIENT_STORAGE - The operation failed due to lack of resources.

The response array returned in the callback may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing IP_Address and interfaceHandle fields.

An NPF_IPV4UC_CbCallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPV4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function call.

4.9.4 NPF_IPV4UC_AddResEntryDelete

Syntax

\[
\text{NPF_error_t NPF_IPV4UC_AddResEntryDelete(}
\begin{align*}
\text{NPF_IN \ NPF\_callbackHandle\_t} & \quad \text{callbackHandle,} \\
\text{NPF_IN \ NPF\_correlator\_t} & \quad \text{correlator,} \\
\text{NPF_IN \ NPF\_errorReporting\_t} & \quad \text{errorReporting,} \\
\text{NPF_IN \ NPF\_IPv4UC\_AddResTableHandle\_t} & \quad \text{tableHandle,} \\
\text{NPF_IN \ NPF\_uint32\_t} & \quad \text{numEntries,} \\
\text{NPF_IN \ NPF\_IPv4UC\_AddResKey\_t} & \quad \text{*entryArray);}
\end{align*}
\]

Description

If an entry exists in the address resolution table as indicated by the IP address and interface pair supplied in an Address Resolution entry contained in the entryArray, then it will be removed from the specified table.

If an Address Resolution entry is removed, a reference to the removed entry by the forwarding plane MAY generate an NPF_IPV4UC_ADD_RES_TBL_MISS event.
This is a required function.

**Input Arguments**
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation.
- tableHandle – Address Resolution table handle.
- numEntries – The number of elements in the entryArray.
- entryArray – A pointer to an array of NPF_IPv4UC_AddResKey_t structures, one for each address resolution table entry to be deleted.

**Output Arguments**
None

**Return Values**
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE – The entries were not deleted from the table because the callback handle was invalid.

**Asynchronous Response**
There may be multiple asynchronous callbacks to this request. An NPF_IPv4UC_AddResKey_t structure will be returned along with a return code. Possible return codes are:
- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST - The operation did not complete successfully since the specified entry was not found.

The response array returned in the call back may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and interface handle fields. An NPF_IPV4UC_CallbackData_t will be returned with each callback. As part of that structure, an array of NPF_IPV4UC_AsyncResponse_t structures will also be returned. If all of the elements in the request array completed successfully and there is no additional response data to return, the callback will return an allOK value of NPF_TRUE, a numResp value of zero, and the array pointer will be null.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be NPF_FALSE, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function calls.
4.9.5  NPF_IPv4UC_AddResTableFlush

**Syntax**

```c
NPF_error_t NPF_IPv4UC_AddResTableFlush(
    NPF_IN NPF_callbackHandle_t     callbackHandle,
    NPF_IN NPF_correlator_t         correlator,
    NPF_IN NPF_errorReporting_t     errorReporting,
    NPF_IN NPF_IPv4UC_AddResTableHandle_t tableHandle);
```

**Description**

All entries in the designated address resolution table will be removed and the designated address resolution table will be left empty.

This is a required function.

**Input Arguments**

- `callbackHandle` - The unique identifier provided to the application when the completion callback routine was registered.
- `correlator` - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- `errorReporting` - An indication of whether the application desires to receive an asynchronous completion callback for this API function call.
- `tableHandle` – Address resolution table identifier.

**Output Arguments**

None

**Return Values**

- `NPF_NO_ERROR` - The operation is in progress.
- `NPF_E_UNKNOWN` - The entries were not deleted from the table due to problems encountered when handling the input parameters.
- `NPF_E_BAD_CALLBACK_HANDLE` - The entries were not deleted from the table because the callback handle was invalid.

**Notes**

This operation removes all entries from the specified table, but does not destroy that table.

If an address resolution entry is removed, a reference to the removed entry by the forwarding plane MAY generate an `NPF_IPV4UC_ADD_RES_TBL_MISS` event.

**Asynchronous Response**

A return code will be returned asynchronously. Possible return codes are:

- `NPF_NO_ERROR` - The operation completed successfully.
- `NPF_IPV4UC_INVALID_HANDLE` - The operation did not complete successfully due to problems with the table handle.
4.9.6 NPF_IPv4UC_AddResTableAttributeQuery

**Syntax**

```c
NPF_error_t NPF_IPv4UC_AddResAttributeQuery(
    NPF_IN NPF_callbackHandle_t               callbackHandle,
    NPF_IN NPF_correlator_t                   correlator,
    NPF_IN NPF_errorReporting_t               errorReporting,
    NPF_IN NPF_IPv4UC_AddResTableHandle_t     tableHandle);
```

**Description**

This call will provide information about the characteristics of the specified address resolution table. Currently, the attributes available are:

- An estimate of how many free entries are in this table.

This is an optional function. Implementations that do not support queries MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

**Input Arguments**

- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API function invocation. The only valid error reporting for this method is NPF_REPORT_ALL.
- tableHandle – Address resolution table identifier.

**Output Arguments**

None

**Return Values**

- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The table was not queried due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The table was not queried because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query capability is not supported by this implementation.

**Notes**

Applications may use this query API function to obtain information useful in maintaining the address resolution table. For example, prior to inserting any address resolution entries into the table, the application might query the available free space of the address resolution table and, therefore, be able to know when it cannot add any more entries to the table.

The implementation SHOULD be conservative in what it returns. In other words, the value should be the amount of free space under the worst-case conditions, so that the application can be assured that at least this many “Add” requests will succeed.

The errorReporting parameter, included for the sake of consistency, is ignored. This function generates an asynchronous response, regardless of the value given in the errorReporting parameter.
Asynchronous Response
A return code will be returned asynchronously along with an approximation of the number of free entries left in the address resolution table. The tableSpaceRemaining field in the NPF_IPv4UC_AsyncResponse_t struct will be set. Possible return codes are:

- NPF_NO_ERROR - The operation completed successfully.
- NPF_IPV4UC_INVALID_HANDLE - The operation did not complete successfully due to problems with the table handle.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The attribute query function for the address resolution table is not supported by this implementation.

4.9.7 NPF_IPv4UC_AddResEntryQuery
Syntax

NPF_error_t NPF_IPv4UC_AddResEntryQuery(
    NPF_IN NPF_callbackHandle_t           callbackHandle,
    NPF_IN NPF_correlator_t               correlator,
    NPF_IN NPF_errorReporting_t           errorReporting,
    NPF_IN NPF_IPV4UC_AddResTableHandle_t tableHandle,
    NPF_IN NPF_uint32_t     numEntries,
    NPF_IN NPF_IPV4UC_AddResKey_t   *entryArray);

Description
This function call is used to query one or more address resolution entries in the address resolution table. If the entries exist, the content of the entries are returned in the completion callback.
This is an optional function. Implementations that do not support queries MUST implement a stub of this function and MUST either immediately return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED when called or MUST return NPF_IPV4UC_FUNCTION_NOT_SUPPORTED in the returnCode field of the asynchronous callback structure.

Input Arguments
- callbackHandle - The unique identifier provided to the application when the completion callback routine was registered.
- correlator - A unique application invocation value that will be supplied to the asynchronous completion callback routine.
- errorReporting - An indication of whether the application desires to receive an asynchronous completion callback for this API invocation.
- tableHandle – Address resolution table identifier.
- numEntries – The number of entries in the entryArray.
- entryArray - Pointer to the array of address resolution keys to query.

Output Arguments
None

Return Values
- NPF_NO_ERROR - The operation is in progress.
- NPF_E_UNKNOWN - The entries were not queried due to problems encountered when handling the input parameters.
- NPF_E_BAD_CALLBACK_HANDLE - The entries were not queried because the callback handle was invalid.
- NPF_IPV4UC_FUNCTION_NOT_SUPPORTED – The query capability is not supported by this implementation.
Asynchronous Response

There may be multiple asynchronous callbacks to this request. An `NPF_IPv4UC_AddResQueryResp_t` structure will be returned along with a return code. Possible return codes are:

- `NPF_NO_ERROR` - The operation completed successfully.
- `NPF_IPV4UC_IN_INVALID_HANDLE` - The operation did not complete successfully due to problems with the table handle.
- `NPF_IPV4UC_TABLE_ENTRY_DOES_NOT_EXIST` - The operation did not complete successfully since the specified entry was not found.
- `NPF_IPV4UC_FUNCTION_NOT_SUPPORTED` - The entry query function call is not supported by this implementation.

The response array returned in the call back may contain between zero and the number of elements requested with this API function call. Each element in the response array can be correlated with an element in the request array by comparing the IP address and interface handle fields.

An `NPF_IPV4UC_CallbackData_t` will be returned with each callback. As part of that structure, an array of `NPF_IPV4UC_AsyncResponse_t` structures will also be returned. Because this function call will always return information that was requested, if all of the elements in the request array completed successfully and there is no additional data to return, the callback will return an allOK value of `NPF_FALSE`, a numResp value equal to the number of responses, and the array pointer pointing to the responses.

If not all of the responses are complete or if not all of the responses were successful or if there is additional response data to return, allOK will be `NPF_FALSE`, the numResp field will be greater than zero, and the pointer to the element array will be non-null. Failing elements may be determined by examining the return code in each array element.

It is the implementation’s choice how many responses to return in a single callback. The minimum is one and the maximum is the number of request elements passed in the original API function calls.
5  API Call and Event Capabilities
These tables are included as a summary for informative purposes.

5.1  Common Function Calls

<table>
<thead>
<tr>
<th>API function Name</th>
<th>Function Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>NPF_Ipv4UC_CallBackFunc</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_EventCallFunc</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_Register</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_Deregister</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_EventRegister</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_EventDeregister</td>
<td>Required</td>
</tr>
<tr>
<td>NPF_Ipv4UC_Get_SupportedModes</td>
<td>Required</td>
</tr>
<tr>

/*
 * This structure is passed to the application as a parameter on a registered
 * completion callback. The type field indicates which function invocation
 * led to this response. The other three fields contain values depending
 * upon the invoking function, whether or not a single operation was
 * requested and whether the operations were successful or not.
 *
 * There are several possibilities:
 *
 * The application invokes a function requesting a single operation:
 * - If allOK = TRUE, then numResp = 0 and the "resp" pointer is NULL.
 *   This indicates the operation completed successfully and there is
 *   no other additional response data to return.
 * - If allOK = FALSE, then numResp = 1 and the "resp" pointer points to
 *   a response structure. If the returnCode field indicates NPF_NO_ERROR,
 *   the operation completed successfully and there is additional response
 *   data in the structure. Otherwise, the operation failed and the reason
 *   is indicated by the returnCode.
 *
 * The application invokes a function requesting multiple operations:
 * - If all operations completed successfully at the same time and there
 *   is no additional response data to provide, then allOK = TRUE,
 *   numResp = 0 and the "resp" pointer is NULL.
 * - If all operations completed successfully at the same time, but there
 *   is additional response data to provide, then allOK = FALSE, numResp
 *   indicates the total number of requested operations and the "resp"
 *   pointer points to an array of response structures. The returnCode
 *   field will indicate NPF_NO_ERROR.
 * - If some operations completed, but not all, then:
 *   > allOK = FALSE, numResp = the number of request operations
 *      completed.
 *   > The "resp" pointer will point to an array of response structures, each
 *      one containing one element for each completed request. For
 *      operations that completed successfully, the returnCode field will
 *      indicate NPF_NO_ERROR and additional response data may be present,
 *      depending on the type of function invocation. For operations that
 *      failed, the reason is indicated by the returnCode field.
